

Adding and Changing Videos and Passwords

Within the site's JS file is an array called allCodes.

Each is a paired code and url.

The current videos are attached to the original drive.

You can host new videos on other sites, such as your own google drive, and link them with the url to display them.

You can have any number of video and code combinations working within the array.

You can freely add new elements to the array that will pull up videos when a code is entered.

Each code will pull up the linked video.

The two exceptions are loss videos. If you want to generate a new start or loss video, change only the URL for the {INITIAL} or {LOSS} codes respectively.

If you change the number of codes, you may also have to change line 82 or line 91 to reflect the new order. Line 82 should have the next-to-last video and line 91 should have the last video.

Adjusting Site Details

All native site elements can be edited with HTML and CSS within the index.html and style.css sheets respectively. This includes the hash popup, which can display any information with edits.
